# Payback Methods

• The **payback method** asks the basic question: How quickly does the alternative pay back its original investment?

|      | Scen        | ario 1      | Scen        | Scenario 2  |  |  |
|------|-------------|-------------|-------------|-------------|--|--|
|      | Annual      | Accumulated | Annual      | Accumulated |  |  |
| Year | Flow        | Net Flow    | Flow        | Net Flow    |  |  |
| 0    | -240,854.40 | -240,854.40 | -188,354.40 | -188,354.40 |  |  |
| 1    | 69,450.83   | -171,403.57 | 55,172.99   | -133,181.41 |  |  |
| 2    | 70,145.34   | -101,258.23 | 55,724.72   | -77,456.69  |  |  |
| 3    | 70,846.79   | -30,411.44  | 56,281.96   | -21,174.73  |  |  |
| 4    | 71,555.27   | 41,143.83   | 56,844.78   | 35,670.05   |  |  |
| 5    | 72,270.81   | 113,414.64  | 57,413.23   | 93,083.28   |  |  |
| 6    | 72,993.52   | 186,408.16  | 57,987.36   | 151,070.64  |  |  |
| 7    | 73,723.46   | 260,131.62  | 58,567.24   | 209,637.88  |  |  |
| 8    | 74,460.69   | 334,592.31  | 59,152.91   | 268,790.79  |  |  |

イロト イポト イヨト イヨト

• The exact payback period for Secnario 1 is computed as

$$PB = 3 + \left(\frac{-30,411.44 - 0}{-30,411.44 - 41.143.83}\right) \times (4 - 3) = 3.425$$
(1)

of course this degree of precision is somewhat dubious.

- The same estimate for Scenario 2 is 3.373. So both of these investments have nearly identical payback periods.
- Under the payback method, investments with shorter payback periods are preferred to investments with longer payback periods.
- One way to interpret this rule is as extreme risk aversion.

< ロ > < 同 > < 回 > < 回 >

# Internal Rate of Return

- The **internal rate of return** is a specialized reformulation of net present value.
- Starting with the simple present value problem

$$NPV = -2,000 + \frac{1,150}{(1.08)} + \frac{1,250}{(1.08)^2} = 126.38.$$
 (2)

- Given what we know about net present, value an increase in the discount rate would result in a lower net present value.
- Increasing the discount rate to 9 percent would reduce the net present value to \$ 98.30.
- Intuitively, there exists a discount rate for which the net present value is equal to zero (in this case 13 percent).

< ロ > < 同 > < 回 > < 回 > < 回 > <

Computation of the Internal Rate of Return

 $\bullet$  We start by replacing  $1/\left(1+r\right)$  in Equation  $\,2$  with  $\delta$  and reorder the expression to yield

$$NPV = 1,250\delta^2 + 1,150\delta - 2,000 = 0$$
 (3)

so that we can solve for the internal rate of return applying the quadratic formula to Equation 3 yielding

$$\delta = \frac{-1,150 \pm \sqrt{1,150^2 - 4(1,250)(-2,000)}}{2(1,250)} = \{0.8859, -1.8060\}$$
(4)

イロト イポト イヨト イヨト

The internal rate of return problem in this case (two period) has two solutions.

• To determine the internal rate of return

$$\delta = \frac{1}{(1+r)} \Rightarrow r = \frac{1}{\delta} - 1.$$
(5)

<ロト < 同ト < ヨト < ヨト

In this case  $\delta = 0.8859 \Rightarrow r = 0.1288$  while for  $\delta = -1.8060 \Rightarrow -1.5537$ .

• One might say: Obviously the first outcome is the investment's internal rate of returninternal rate of return. However, the question remains why?

- Consider a somewhat more complicated cash flow stream investment I in the preceeding lecture.
- We would determine the internal rate of return by solving

$$NPV = 3,120\delta^4 + 3,210\delta^3 + 3,290\delta^2 + 3,380\delta - 10,500 = 0.$$
(6)

This equation has four solutions (by the fundamental theorem of polynomials), but unlike the quadratic its solutions do not have a closed form.

< ロ > < 同 > < 回 > < 回 >

 $\bullet\,$  The numerical results for  $\delta$  in Equation  $\,$  6 are

$$\delta = \begin{cases} -1.6056\\ -0.1693 - 1.5039i\\ -0.1693 + 1.5039i\\ 0.9153 \end{cases}$$
(7)

・ロト ・ 一下・ ・ ヨト・

Э

DQ P

Clearly, in this example, the feasible delta is 0.9153 implying an internal rate of return of 0.0926.

Payback Method Internal Rate of Return Benefit Cost Analysis

### Internal Rates of Returns for Sample Investments

| Investment | IRR    | ANPV   |  |
|------------|--------|--------|--|
| I          | 0.0926 | 88.09  |  |
| J          | 0.0865 | 60.01  |  |
| K          | 0.1015 | 242.63 |  |
| K          | 0.0898 | 122.51 |  |

# Benefit Cost Analysis

- Another method for analyzing investment popular in policy and development analysis is the benefit cost approach.
- The **benefit cost** approach essentially divides present value of the revenue stream (or benefits) by the present of required capital outlays (or costs).

$$B/C = \frac{\sum_{i=0}^{N} \frac{B_i}{(1+r)^i}}{\sum_{i=0}^{N} \frac{C_i}{(1+r)^i}}.$$
(8)

 If the benefit to cost ratio is greater than one, the investment is determined to be "profitable" or "beneficial" to the economy. Payback Method Internal Rate of Return Benefit Cost Analysis
